Controller layed Annotation :

1 - @Controller :- It indecates that the class is responsible for handling incomming HTTP requests.

2 - @ RestController :-

RestController = Controller + ResponseBody

↓

Response-body tell us this is not a view it's us a ~~respo~~ HTTP Respons body and send as it es.

3 :- @ RequestMapping :- used to map the web request to its handler class or its handler method.

* When we use as a Class level, It can provide the common path on top level.

* When we use to method level, It can provid the specific path for specific request.

1 :- value, path (both are same)
2) Method
3) Consumes, produces.
4) @ Mapping
5) @ Reflective (ControllerMappingReflectiveProcessor.cl

Concept&& Coding

```
@RequestMapping(path = "/fetchUser", method = RequestMethod.GET,
                consumes = "application/json", produces = "application/
                                                            Json")
```

5:- RequestParam :- Use the bind request parameter to Controller method parameter.

http://localhost:8080/api/fetchUser?firstName=HIMANSHU&lastName=SINGH.

path

1

* ~~By. It is present~~ in

* In request mapping it is present By Default. required = true
If value is not present value is not envoked.

* If we passed requird = false. It consider as null.

6:- @Path variable :- Use to extract values from the path ~~from~~ of the URL and help to bind it to Controller method parameter.

Concept && Coding

7: @RequestBody :- Bind the body of HTTP request (typically Json) to Controller method parameter (Java object)

8:- ResponseEntity :- It represent the Entire HTTP response, Header, status, response body etc.

Lecture 5

Spring Boot Bean and it's Lifecycle

What is bean?

- In ~~Sip~~ Simple term, Bean is a java object, which in managed by Spring container (also know as IOC Container)

* IOC Container -> Contains all the beans which get created and also manage them.

How to create a Bean?

- @Component Annotation
- @Bean Annotation

Concept && Coding
